

AMENDMENTS TO THE CLAIMS

Claims 1-45 (Canceled).

46. (Previously Presented) The rewinding machine as claimed in claim 49, wherein said severing device further comprises a blade applied along said aperture with which said movable element cooperates.

47. (Previously Presented) The rewinding machine as claimed in claim 46, wherein said blade is fitted along an edge of said aperture disposed downstream with respect to a movement to unload the log on said chute.

48. (Previously Presented) The rewinding machine as claimed in claim 46 or 47, wherein said blade is serrated.

49. (Previously Presented) Rewinding machine to produce logs of web material comprising:

- a winding cradle;
  - an insertion member to insert a winding core into said winding cradle;
  - an ejector to eject a log formed in said winding cradle by causing the log to roll on an unloading chute;
  - a severing device to sever the web material after the log is ejected from said winding cradle;
- wherein

- disposed along the unloading chute is an aperture elongated in a direction transverse to a direction in which the log is unloaded along said unloading chute;

- said severing device comprises a movable element that is inserted into said aperture to cause severing of the web material between the winding cradle and the log of wound web material, and

- a first glue container is disposed underneath said unloading chute and wherein a first movable dispensing member that collects glue from said first glue container to apply the glue to the log of wound web material is associated with said first glue container.

50. (Previously Presented) The rewinding machine as claimed in claim 49, further comprising rewinding means to wind a trailing edge of the log after the glue has been applied.

51. (Previously Presented) The rewinding machine as claimed in claim 50, wherein said rewinding means define a stop position of the log ejected onto said unloading chute, the glue being applied to the log when the log is in said stop position.

52. (Previously Presented) The rewinding machine as claimed in claim 49, wherein said aperture has a width in a

direction in which said log is unloaded such that when the movable element of the severing device is in said aperture, said first movable dispensing member can pass through said aperture.

53. (Previously Presented) The rewinding machine as claimed in claim 49, wherein said movable element is carried by a pair of oscillating arms.

54. (Previously Presented) The rewinding machine as claimed in claim 53, wherein said pair of oscillating arms supports a winding roller with movable axis.

55. (Previously Presented) The rewinding machine as claimed in claim 49, wherein a second glue container is disposed underneath said winding cradle and wherein a second movable dispensing member to apply a glue to the winding core when the winding core is in said winding cradle, is associated with said second glue container.

56. (Previously Presented) Rewinding machine to produce logs of web material comprising:

- a winding cradle;
- an insertion member to insert a winding core into said winding cradle;
- an ejector to eject a log formed in said winding cradle by causing the log to roll on an unloading chute;

6392/USSN 10/510,576  
Group Art Unit 3654

- a severing device to sever the web material after the log is ejected from said winding cradle;

wherein

- disposed along the unloading chute is an aperture elongated in a direction transverse to a direction in which the log is unloaded along said unloading chute;

- said severing device comprises a movable element that is inserted into said aperture to cause severing of the web material between the winding cradle and the log of wound web material,

- an insertion surface for the winding core is disposed on an opposed side of said winding cradle with respect to the unloading chute, said insertion member being constructed and arranged to push the winding core along said insertion surface towards said winding cradle, and

- said ejector and said insertion member are integral with each other.

57. (Previously Presented) Rewinding machine to produce logs of web material comprising:

- a winding cradle;

- an insertion member to insert a winding core into said winding cradle;

- an ejector to eject a log formed in said winding cradle by causing the log to roll on an unloading chute;
  - a severing device to sever the web material after the log is ejected from said winding cradle;
- wherein
- disposed along the unloading chute is an aperture elongated in a direction transverse to a direction in which the log is unloaded along said unloading chute;
  - said severing device comprises a movable element that is inserted into said aperture to cause severing of the web material between the winding cradle and the log of wound web material, and
  - said ejector and said insertion member are integral with each other.

58. (Previously Presented) The rewinding machine as claimed in claim 56 or 57, wherein said insertion member is provided with a translatory movement.

59. (Previously Presented) The rewinding machine as claimed in claims 56 or 57, wherein said ejector comprises a pair of sides between which a pusher section extends to eject the log of wound web material from said cradle, and with which the insertion member is integral, the ejector and the insertion member being spaced from each other in a

direction of movement to insert the winding core and to eject the log, and wherein means to feed the winding core are provided to position said winding core in an intermediate position between the insertion member and the ejector.

60. (Previously Presented) The rewinding machine as claimed in claim 59, wherein said means to feed the winding core comprise a channel to drop the winding core, defining an insertion trajectory orthogonal to an axis of said winding core.

61. (Previously Presented) The rewinding machine as claimed in claim 60, wherein said means to feed the cores further comprise a conveyor that inserts said winding core with a movement parallel to the axis of said winding core.

62. (Previously Presented) The rewinding machine as claimed in claim 61, wherein said conveyor comprises a belt conveyor.

63. (Previously Presented) The rewinding machine as claimed in claim 49, wherein said first movable dispensing member comprises an elongated member provided with an oscillating movement.

64. (Previously Presented) The rewinding machine as claimed in claim 55, wherein said second movable dispensing

member comprises an elongated member provided with an oscillating movement.

65. (Previously Presented) The rewinding machine as claimed in claim 50, wherein said rewinding means include a pair of rewinding rollers.

66. (Previously Presented) The rewinding machine as claimed in claim 65, wherein a first one of said rewinding rollers is supported by a pair of oscillating arms to be carried from an active position to a disabled position.

67. (Previously Presented) The rewinding machine as claimed in claim 66, wherein a conveyor is disposed between the disabled position of said first one of said rewinding rollers and a second one of said rewinding rollers to move the log of wound web material away in a direction parallel to an axis of the log.

68. (Previously Presented) The rewinding machine as claimed in claim 49, 54 or 57, further comprising a plurality of cutting knives to cut the web material along longitudinal cutting lines, cooperating with respective counter-blades constituted by a plurality of annular channels produced on a counter-roller.

69. (Previously Presented) The rewinding machine as claimed in claim 68, further comprising a series of ply-bonding members, cooperating with said counter-roller.

70. (Previously Presented) The rewinding machine as claimed in claim 49, 54 or 57, wherein said winding cradle is formed of a pair of winding rollers.

71. (Previously Presented) The rewinding machine according to claim 49, 54 or 57, wherein said movable element includes a severing member and yieldable side members.

72. (Previously Presented) The rewinding machine according to claim 49, wherein said first glue container is arranged underneath said aperture.

73. (Previously Presented) The rewinding machine according to claim 72, wherein said movable dispensing member moves from said first glue container towards said log and passes through said aperture into which said movable element enters to sever the web material.

74. (Previously Presented) The rewinding machine according to claim 49 or 72, wherein along said unloading chute a second aperture is provided, arranged parallel to said aperture into which said movable element enters to

sever said web material, said second aperture providing a passage for said first movable glue dispensing member.

75. (Previously Presented) The rewinding machine according to claim 49, 54 or 57, wherein said movable element is carried by a first pair of oscillating arms and wherein a second pair of oscillating arms is provided which carry a third winding roller.

76. (Canceled).

77. (Previously Presented) The method as claimed in claim 80, wherein said movable element cooperates with a blade fitted along said aperture to sever the web material.

78. (Previously Presented) The method as claimed in claim 80, wherein a movable winding roller is brought into contact with said at least one second winding core.

79. (Previously Presented) The method as claimed in claim 80, wherein said movable element is moved in said aperture to sever the web material simultaneously to said movable winding roller when the movable winding roller is brought into contact with the at least one second winding core.

80. (Previously Presented) Method of producing logs of web material, comprising:

- inserting at least one first winding core into a winding cradle;
  - winding a pre-established quantity of web material around said at least one first winding core to form a log;
  - unloading the log from said winding cradle along an unloading chute;
  - inserting at least one second winding core into said winding cradle;
  - severing the web material between said log and said at least one second winding core by means of a severing device;
- wherein
- disposed along said unloading chute is an aperture, elongated in a direction transverse to a direction in which the log is unloaded along said unloading chute;
  - severing said web material by a movable element of said severing device by inserting said movable element into said aperture, and
  - a first glue container is disposed underneath said aperture; and a glue is applied by a first movable dispensing member to the log unloaded onto said unloading chute, said first movable dispensing member collecting the glue from said first container.

81. (Previously Presented) Method of producing logs of web material, comprising:

- inserting at least one first winding core into a winding cradle;
  - winding a pre-established quantity of web material around said at least one first winding core to form a log;
  - unloading the log from said winding cradle along an unloading chute;
  - inserting at least one second winding core into said winding cradle;
  - severing the web material between said log and said at least one second winding core by means of a severing device;
- wherein
- disposed along said unloading chute is an aperture, elongated in a direction transverse to a direction in which the log is unloaded along said unloading chute;
  - severing said web material by a movable element of said severing device by inserting said movable element into said aperture,
  - applying a glue to said at least one second winding core when the at least one second winding core is in the winding cradle, and

- winding is started on said at least one second winding core while the severing device is still in a severing position.

82. (Previously Presented) The method as claimed in claim 83 or 90, wherein said glue is applied to the at least one second winding core during severing of the web material.

83. (Previously Presented) Method of producing logs of web material, comprising:

- inserting at least one first winding core into a winding cradle;

- winding a pre-established quantity of web material around said at least one first winding core to form a log;

- unloading the log from said winding cradle along an unloading chute;

- inserting at least one second winding core into said winding cradle;

- severing the web material between said log and said at least one second winding core by means of a severing device;

wherein

- disposed along said unloading chute is an aperture, elongated in a direction transverse to a direction in which the log is unloaded along said unloading chute;

- severing said web material by a movable element of said severing device by inserting said movable element into said aperture,

- applying a glue to said at least one second winding core when the at least one second winding core is in the winding cradle, and

- the glue is applied to the at least one second winding core by a second movable dispensing member that collects glue from a second glue container disposed underneath said winding cradle.

84. (Previously Presented) The method as claimed in claim 83 or 90, wherein said at least one second winding core is disposed at an insertion surface positioned, with respect to the winding cradle, on a side opposed to said unloading chute, before unloading the log from the winding cradle.

85. (Previously Presented) Method of producing logs of web material, comprising:

- inserting at least one first winding core into a winding cradle;

- winding a pre-established quantity of web material around said at least one first winding core to form a log;

6392/USSN 10/510,576  
Group Art Unit 3654

- unloading the log from said winding cradle along an unloading chute;
  - inserting at least one second winding core into said winding cradle;
  - severing the web material between said log and said at least one second winding core by means of a severing device;
- wherein
- disposed along said unloading chute is an aperture, elongated in a direction transverse to a direction in which the log is unloaded along said unloading chute;
  - severing said web material by a movable element of said severing device by inserting said movable element into said aperture, and
  - unloading the log from said winding cradle and inserting said at least one second winding core into said winding cradle by an ejector and an insertion member, respectively, which are integral with each other.

86. (Previously Presented) The method as claimed in claim 83 or 90, wherein said web material is formed of at least two plies; wherein said at least two plies are bonded together by ply-bonding; and wherein the web material is

divided into a plurality of longitudinal strips before winding.

87. (Previously Presented) The method as claimed in claim 86, wherein the web material is divided by cutting the web material using a series of cutting knives cooperating with a single counter-roller, which is provided with annular grooves forming counter-blades for said cutting knives, separated from one another by annular projections at least some of which cooperate with gripping members.

88. (Previously Presented) Method according to claim 87, wherein said web material is retained during said cutting by pressing the web material near edges of said aperture.

89. (Currently Amended) Rewinding machine to produce logs of web material comprising:

- a winding cradle;
- an insertion member to insert a winding core into said winding cradle;
- an ejector to eject a log formed in said winding cradle by causing the log to roll on an unloading chute;
- a severing device to sever the web material after the log is ejected from said winding cradle;

wherein

- a glue container is arranged underneath said winding cradle, and wherein a movable dispensing member is associated with said glue container to apply a glue to the winding core when the winding core is in said winding cradle; and

wherein

- disposed along the unloading chute is an aperture elongated in a direction transverse to a direction in which the log is unloaded along said unloading chute;

- said severing device comprises a movable element that is inserted into said aperture to cause severing of the web material between the winding cradle and the log of wound web material;

- said movable element is carried by a pair of oscillating arms; and

- said pair of oscillating arms supports a winding roller with movable axis.

90. (Currently Amended) Method of producing logs of web material, comprising:

- inserting at least one first winding core into a winding cradle;

- winding a pre-established quantity of web material around said at least one first winding core to form a log;

6392/USSN 10/510,576  
Group Art Unit 3654

- unloading the log from said winding cradle along an unloading chute;
  - inserting at least one second winding core into said winding cradle;
  - severing the web material between said log and said at least one second winding core by means of a severing device;
- wherein
- disposed along said unloading chute is an aperture, elongated in a direction transverse to a direction in which the log is unloaded along said unloading chute;
  - severing said web material by a movable element of said severing device by inserting said movable element into said aperture;
  - applying a glue to said at least one second winding core when the at least one second winding core is in the winding cradle; and
  - the glue is applied simultaneously on substantially an entire length of the winding core by a movable dispensing member which obtains the glue from a glue container disposed underneath the winding cradle.
